

Existing Issues and Reflection of Iteration 2

Auth Module

The authentication module can already support basic login and registration functions. However, after the second iteration, several issues still remain in role management, interaction design, and security control.

1. The role selection function is still incomplete.

At present, the system mainly supports TA and MO roles, but the admin role is not clearly included in the identity selection process. Since the admin module is responsible for user management, workload evaluation, and data statistics, the lack of an admin entry may affect the normal use of the system. Therefore, the third iteration should add admin as a role option so that different users can enter their corresponding modules correctly.

2. The password field lacks a visible/invisible switch.

Currently, users cannot check the password they have entered during login or registration. This may cause input errors, especially when the password is long or complex. A password visibility toggle should be added to improve usability and reduce repeated login or registration failures.

TA Profile Module

The TA Profile module can now collect basic personal information and skill information. However, the current input method is still too flexible, which may cause inconsistent data and reduce the accuracy of later AI matching.

1. Skill input is too flexible and not standardized.

At present, TAs can freely enter their skills. However, different users may describe the same skill in different ways, such as “Java programming”, “Java”, or “Java language”. This makes it difficult for the system to recognize skills accurately. In the third iteration, a fixed skill pool should be added so that users can select skills from predefined options.

2. The font display of the Profile interface still needs improvement.

Although the basic functions of the Profile page are available, some font sizes, spacing, and visual hierarchy are not clear enough. Users may feel that the page is crowded or that important information is not highlighted. The next iteration should improve font display, layout, and information hierarchy.

TA Job Application Module

The TA Job Application module already supports job browsing and application submission. However, the current process still depends heavily on manual selection and lacks intelligent recommendation and complete status tracking.

1. AI-based job matching for the current TA is missing.

Currently, TAs need to browse jobs by themselves and decide which positions are suitable. The system does not automatically recommend jobs based on the TA's skills, experience, and job requirements. This increases the user's workload and may cause suitable jobs to be missed. In the third iteration, an AI matching function should be added to recommend the top three most suitable jobs for the current TA.

2. Application status tracking is not complete enough.

The current process focuses mainly on application submission. However, later steps, such as MO invitation and TA confirmation, are not clearly tracked. Without complete status tracking, both TA and MO may find it difficult to know whether the final arrangement has been confirmed. Therefore, the third iteration should build a complete flow of "MO invitation → TA confirmation → status update".

MO Job Management Module

The MO Job Management module already allows MOs to create and manage jobs. However, there is still room for improvement in the quality of job descriptions and intelligent assistance.

1. MO lacks assistance when writing course descriptions.

Currently, MOs need to write course descriptions, job requirements, and skill requirements by themselves. If the description is too vague, TAs may find it difficult

to judge whether they are suitable for the position. It may also reduce the accuracy of AI matching. Therefore, the third iteration should add an AI suggestion function to help MOs write clearer and more complete course descriptions.

MO Application Review Module

The MO Application Review module can support basic review actions, but several important functions are still missing, including confirmation and CV viewing.

1. The double check mechanism is still incomplete.

After an MO reviews and selects a TA, the system does not fully support the TA's final confirmation. In the real workflow, the TA should clearly agree to become the teaching assistant for a course. The third iteration should add a double check mechanism to prevent one-sided confirmation.

2. MO lacks an entry to view uploaded CVs.

When reviewing TA applications, MOs need to check the applicant's CV, experience, and skill background. At present, there is no clear entry for viewing uploaded CVs, which makes the review information incomplete. The third iteration should add a CV viewing port for MOs.

Admin Module

1. The workload evaluation rule needs to be updated.

Currently, the system does not clearly prevent one TA from taking too many assistant positions. In the third iteration, the workload rule should be updated so that one student cannot apply for more than three TA jobs. This can prevent excessive workload and make job allocation more reasonable.

2. TA data statistics are not visual enough.

At present, the TA statistics page mainly relies on text or tables. It does not clearly show the distribution of TA workload, applications, or accepted positions. A pie chart should be added to make the data easier for admins to understand.
