

Existing Issues and Reflection of Iteration 3

Dashboard, Navigation Bar and Functional Interfaces

After the third iteration, the main functions of the system have been further improved. However, the overall interface style, navigation experience, and connection with the college's culture still need to be optimized in the fourth iteration.

1. The dashboard still needs overall improvement.

The current dashboard can display some system information, but its visual hierarchy, information layout, and overall appearance are not yet ideal. As the main page users see after entering the system, the dashboard should be clearer, more intuitive, and better at presenting the key functions of the TA recruitment system.

2. The navigation bar still needs to be improved.

The current navigation bar supports basic page switching, but its structure, page positioning, and consistency still need improvement. In the fourth iteration, the navigation bar should be optimized so that users can move between different functional modules more easily.

3. The visual style of different functional interfaces is not unified enough.

After the third iteration, some functional interfaces still have inconsistent styles. Fonts, buttons, spacing, colors, and page layouts need to be further unified.

4. The interface does not fully reflect the college's culture and style.

The current system still looks more like a general management system and does not clearly reflect the college's cultural features or usage context. In the fourth iteration, the overall visual style and page design should be adjusted to make the TA recruitment system better match the college's culture and style.

Auth Module

After the third iteration, the login and registration module has supported more role-related functions, but the admin registration method still needs further adjustment.

1. Admin registration should be changed to an application-based process.

The current method of obtaining an admin role is still not reasonable enough. Since

admin users have higher system permissions, users should not be allowed to directly register as admins. In the fourth iteration, admin registration should be changed into an application-based process, where users can apply to become admins from the login or registration page.

Admin Module

After the third iteration, the admin module has taken on more management functions. However, admin application review and intelligent management support still need further improvement.

1. The admin interface needs an admin application review function.

After users apply to become admins from the login or registration page, existing admins should be able to view and review these applications in the admin interface. Therefore, the fourth iteration needs to add an admin application review function to make the process of granting admin permissions more standardized.

2. The admin module lacks an AI-based system warning function and workload balance suggestions.

Currently, admins mainly rely on manual checking of system data. The system itself cannot actively identify potential problems. In the fourth iteration, an AI function should be added to provide intelligent system warnings and help admins detect possible risks more quickly. Although the system has already considered TA workload issues, admins still lack intelligent decision support. In the fourth iteration, AI should provide workload balance suggestions based on system data, helping admins manage and adjust workload distribution more reasonably.
